2018.8.01	Whole document	JCD: Formatting checks. Movement of Periodic QC described in section 3.8 to the more appropriate section 3.3. Section 3.8 rewritten to capture Image QC element such as visual assessment, trapping motion, ensuring good registration between CT AC and emission data, and ensuring appropriate count levels have been acquired.

## 70 **Open Issues:**

The following issues are provided here to capture associated discussion, to focus the attention of reviewers on topics needing feedback, and to track them so they are ultimately resolved. In particular, comments on these issues are highly encouraged during the Public Comment stage. Uncertainty in some scalar values has been highlighted in yellow throughout the text for the purpose of drawing the field's attention.

- 75 field's attention.
  - Q. Uncertainty and concern pervades using this profile to distinguish, or "discriminate", between patients with neurodegenerative diseases and other causes of parkinsonism, such as essential tremor. Would a discrimination claim be acceptable to the community?
  - A. The SPECT Biomarker Committee suggests discriminatory claims have value, and can be adequately trustworthy when used with caution in the context described. However, some residual stakeholder concerns led to discrimination being described as a "use case" in this version of the profile, which appears in the section on cross sectional claims, but is not labeled as a claim per se.
  - Q. The community cannot agree on a method for distinguishing the anterior from the posterior putamen, but the committee notes that there are several software systems that do this. Their groundwork data and analyses are not available for vetting at this time.
  - A. Enterprises claiming conformance based on distinctions between anterior and posterior putamen will need to describe their own methods and present their own evidence of qualification.
  - Q. Challenges with the linearity of bias.
  - A. Although groundworks have allowed an estimate of bias, we are not currently in a position to assess the linearity of bias. This means that we have had to lose claim 2b which addresses longitudinal change of SBR.

## **Addressed Issues:**

80

The following issues have been considered closed by the biomarker committee. They are provided here to forestall discussion of issues that have already been raised and resolved, and to provide a record of the rationale behind the resolution.

#### Q. Is this template open to further revisions?

A. Yes. This is an iterative process by nature.

Submit issues and new suggestions/ideas to the QIBA Process Cmte.

Q. standards: solid (e.g., Cobalt 57, Tellurium-123) or fillable (e.g., solutions of residual <sup>123</sup>I ioflupane).

A. Decision has been made to go with fillable striatal phantom for this version. There are plans to develop solid phantoms in the future.

Q. Measurand: specific binding ratio or percent injected dose per gram?

A1. start with striatal binding ratio; launch absolute quant during the next iteration.

A2. Decision to delete absolute quant from version 1 implemented on 17 May 2016

#### Q. Are the minimal number of counts known?

**A.** Groundwork sponsored during Round 6 of NBIB funding successfully characterized some of the relationships between counts and quality. See Section 4.2.1

- Q. Scalar values surrounding bias are currently uncertain. We note that there are a range of claims in the literature. We expect the reproducibility of estimates of bias to continue varying as new hardware (e.g., CZT detectors, novel pinhole collimator geometry, innovations in in-line CT, etc.), and signal processing algorithms rapidly evolve.
- A. The issue of bias was mooted for the time being by eliminating any claims that were dependent on knowing the scalar magnitude of bias.

# **1. Executive Summary**

Parkinsonism is a major health problem. Distinguishing neurodegenerative causes of parkinsonism from non-degenerative movement disorders that can mimic Parkinson's disease (PD) has important implications for prognosis and clinical management. The goal of this QIBA Profile is to optimize the performance of Iodine-123 (<sup>123</sup>I) ioflupane single photon emission computed tomography (SPECT) for quantifying the concentration of regional cerebral dopamine transporters (DaT) in patients with
 movement disorders.

The **Claim** (Section 2): This profile claims that conformance with its specifications will provide test-retest technical variance of less than 15% COV. In clinical use this might permit the ability to distinguish true biological change from measurement noise in clinical trials of participants who will be studied cross—sectionally, to aid accurate cohort recruitment and longitudinally with <sup>123</sup>I-ioflupane. The claim is

- 95 founded on observations that neurodegenerative disorders, such as idiopathic PD and Diffuse Lewy Body Dementia (DLBD), are associated with dopaminergic neuronal degeneration, which can be particularly pronounced in the substantia nigra. The degeneration of the axonal projections from the substania nigra to the basal ganglia is manifested as a loss of DaT activity. In most clinical imaging contexts where the question is about a neurodegenerative disorder, the loss is first observed in the most posterior
- aspect of the putamen, and then seems to march anteriorly, with left and right sides showing asymmetric changes. As a result, quantifying DaT can distinguish normal and abnormal states.

The **Activities** (Section 3) describe what needs to be done to make measurements that reliably distinguish patients from controls with confidence. Requirements are placed on the **Actors** who participate in those activities as necessary to achieve the Claim.

- 105 **The Assessment Procedures** (Section 4) for evaluating specific requirements are defined as needed. This QIBA Profile, "Quantifying Dopamine Transporters with <sup>123</sup>Iodine Labeled Ioflupane in Neurodegenerative Disease", addresses quantitative SPECT imaging, which is often used as a diagnostic, as well as a longitudinal biomarker of disease progression or response to treatment. It places requirements on Acquisition Devices, Technologists, Radiologists, Reconstruction Software and Image
- 110 Analysis Tools involved in Subject Handling, Image Data Acquisition, Image Data Reconstruction, Image QA and Image Analysis.

The requirements are focused on achieving sufficient accuracy and avoiding technical variability of the DaT measurements to distinguish neurodegenerative causes of parkinsonism from non-degenerative causes.

115 The clinical performance target is to achieve a 95% confidence interval for the striatal binding ratio with both a reproducibility and a repeatability of +/- 15%.

This document is intended to help clinicians basing decisions on this biomarker, imaging staff generating this biomarker, vendor staff developing related products, purchasers of such products, and investigators designing trials with imaging endpoints.

120 Note that this document only states requirements to achieve the claim, not "requirements on standard of care". Conformance to this Profile is secondary to properly caring for the patient.

This QIBA Profile, and others like it addressing CT, MRI, PET and ultrasound can be found at www.qibawiki.rsna.org .

## 125 **2. Clinical Context and Claims**

## **Clinical Context**

Parkinson's disease (PD) and Diffuse Lewy Body Dementia (DLBD) are major health problems. The prevalences are increasing as the population ages. Onset can be insidious, which can make the diagnosis challenging on clinical grounds alone. A number of radiopharmaceuticals that can quantify several

- 130 different components of the pre-synaptic dopamine system have been shown to help distinguish, or "discriminate", between neurodegenerative causes, such as idiopathic PD, and movement disorders like essential tremor that mimic it. In addition, clinical research therapeutic trials employ quantitative DaT SPECT in effort to improve diagnostic reliability for trial eligibility and longitudinal monitoring of putative neuroprotective agents. . Ensuring appropriate diagnosis for clinical trial eligibility has become
- 135 important need given the trials are occurring earlier and earlier in the course of the disease process when diagnosis is most troublesome. This profile focuses on a marketed radiopharmaceutical for this use, Iodine-123 (<sup>123</sup>I) labeled ioflupane (methyl (1R,2S,3S,5S)- 3-(4-iodophenyl)- 8-(3-fluoropropyl)- 8azabicyclo[3.2.1]octane- 2-carboxylate).

### 140 Conformance to this Profile by all relevant staff and equipment supports the following claim:

## **Claim 1: Technical performance claims**

# Claim 1a. Measurement of the specific binding ratios (SBR) of striata have a within subject Coefficient of Variation (wCV) of 15%.

\*The wCV was estimated from a phantom experiment where 5 repeat measurements were performed of a striatal phantom on two systems. SBR was determined for L Caudate, L Putamen, R Caudate and R Putamen. The 95% CIs for the wCV varied around [6%, 11%], depending on the degree of corrections performed. The 15% value chosen for the claim reflects recognition of the additional variability in human subjects.

#### 150

145

# Claim 1b: Measurement of the caudate:putamen activity concentration ratio has a within subject Coefficient of Variation (wCV) of 8%.

\* The wCV was estimated from a phantom experiment where 5 repeat measurements were performed of a striatal phantom on two systems. The estimated wCV from that experiment was 5.6% with 95% CI of [3.8%, 10.7%].

#### 155

## Caveats of Context. These claims hold when:

- Clinical evaluation finds no other cause of parkinsonism, such as recent exposure to known toxins that can present with movement disorders, such as MPTP
- Anatomical imaging, such as magnetic resonance imaging (MRI), has already ruled out other causes of parkinsonism, such as stroke;
- The patient has not been taking drugs or nutritional supplements that can transiently influence the measurements, such as dopamine transporter antagonists
- The patient does not have a deformity or condition that prevents proper positioning in the scanner, such as a severe kyphosis;

- 165 The patient can tolerate the imaging procedures well enough to prevent motion from ٠ confounding the acquisition;
  - The administration of the radiopharmaceutical is not confounded by infiltration of the dose;
  - And other such conditions, which, in the opinion of the professional staff, confound the examination.
- 170 Note that a change of 42% is required when considering an individual patient in isolation. Well-• powered clinical trials will be able to detect mean changes much smaller than 42%.

#### Discussion

The primary measurand, or outcome measure, is the specific binding ratio (SBR) obtained in the 175 striatum. The measurand is usually divided into separate values for the caudate, anterior putamen, and posterior putamen. While research studies sometimes include the SBR for other structures, such as the substantia nigra pars compacta, the thalamus, amygdala, hippocampus, and cortical gray matter, these regions are beyond the scope of this profile.

The SBR is defined as the count density in a striatal volume of interest (VOI) minus the count density in 180 in a reference region divided by the count density in the reference region, which is often expressed in an equivalent form as the count density in a striatal VOI divided by a count density in a reference region VOI minus 1, and is roughly equivalent to the binding potential (BPnd) using a reference region as estimate of non-displaceable uptake in basal ganglia.

The reference region is ideally the cerebellum, as it contains no known dopaminergic proteins or 185 messenger RNA for these proteins. Acceptable alternatives include the occipital cortex, particularly when the axial field of view is limited.

An alternative outcome measure is the fraction of the injected dose per unit volume in a VOI expressed in units of kBg/mL. This measure is an estimate of transporter number, rather than transporter density. And, it might be an ideal outcome measure in some settings. However, this profile does not mandate

190 absolute quantification.

> These claims are based on estimates of the within-subjects coefficient of variation (wCV) for SBRs in the basal ganglia. In the claim statement, the CI is expressed as  $Y \pm 1.96 \times Y \times wCV$ . The claim assumes that the wCV is constant for each component of the basal ganglia (e.g., head of caudate and anterior putamen) in the specified size range, and that there is negligible bias in the measurements (i.e., bias

195 after all corrections is < 15%). For estimating the critical % change, the % Repeatability Coefficient (%RC) is used: 2.77 × wCV × 100.

The +/- 15% boundaries can be thought of as "error bars" or "noise" around the measurement of SBR change. If an operator measures change within this range, it cannot be certain that there has really been a change. However, if a SBR changes beyond these limits, then an observer can be 95% confident there

200 has been a true change in the SBR, and the perceived change is not just measurement variability. Note that this does not address the biological significance of the change, just the likelihood that the measured change is real.

Clinical interpretation with respect to the magnitude of true change:

The magnitude of the true change is defined by the measured change and the error bars (+/- 15%). If an 205 operator measures the SBR to be 3.0 at baseline and 1.5 at follow-up, then the measured change is a 50% decrease in SBR (i.e., 100x(3.0 - 1.5)/3.0). The 95% confidence interval for the true change in SBR is

 $(1.5 - 3.0) \pm 1.96\sqrt{(1.5 \times 0.077)^2 + (3.0 \times 0.077)^2}$ , or [-2.01, -0.99], which represents a 33% to 67% decrease in SBR.

210 Statement of Use: Cross Sectional Discrimination. Note: This statement of use is proffered with caution on an experimental basis. QIBA encourages all stakeholders to comment. Data supporting or refuting this use are particularly welcome.

The ability of measurements made in conformance with this profile to discriminate between relevant groups holds when assessing patients during their initial presentations of parkinsonian symptoms, if, but

- 215 only if, the requirements for quantitative DAT scanning defined in this Profile are met, and the constraints around the clinical context described in this section are valid. If the measurements conform to the requirements of this profile, then measurements of SBR in the posterior putamen that are either (a) 50% or less than the value in aged-matched controls, or (b) 80% or less than the value in the whole striatum are diagnostic for a neurodegenerative cause of the symptoms with a sensitivity of at least 85%
- and specificity of at least 80%,\* provided none of the contextual caveats described below are violated.
   Longitudinal Change. Clinical interpretation with respect to progression or response:
   A decrease in SBR that exceeds the lower bound of the confidence interval indicates there is a 95% probability of disease progression. An increase in SBR that exceeds the upper bound has a 95% chance of representing a true biological change in the concentration of DaT. The medical implications of
- 225 changes that are greater than the bounds of the confidence interval are beyond the scope of this profile. While the cross sectional power of discrimination between patients with dopaminergic neurodegenerative diseases and patients without neurodegenerative diseases described by Claim 1 has been informed by an extensive review of the literature and expert consensus, it has not yet been fully substantiated by studies that strictly conform to the specifications given here. The expectation is that
- 230 during field testing, data on actual performance will be collected, and any appropriate changes that are indicated will be made to the claim or the details of the Profile. At that point, this caveat may be removed, refined, or re-stated.

\*These sensitivity and specificity values represent lower 95% confidence bounds.

# **3. Profile Activities**

The Profile is documented in terms of "Actors" performing "Activities". Equipment, software, staff or sites may claim conformance to this Profile as one or more of the "Actors" in the following table.

240 Conformant Actors shall support the listed Activities by conforming to all requirements in the referenced Section.

Actor	Activity	Section
Acquisition Device	Pre-delivery	3.1.
Dhusisist	Acceptance tests	3.2
Physicist	Periodic QA/QC	3.3
Clinician	Subject Selection	3.4
	Subject Handling	3.5.
	Image Data Acquisition	3.6.
Technologist	Image Data Reconstruction	3.7.
	Image QA	3.8.
	Image Distribution	3.9.
Reconstruction Software	Image Data Reconstruction	3.7.
Image Analyst	Image Analysis	3.10.

Table 1: Actors and F	<b>Required Activities</b>
-----------------------	----------------------------

The requirements in this Profile do not codify a Standard of Care; they only provide guidance intended to achieve the stated Claim. Failing to conform to a "shall" declaration in this Profile could be a protocol deviation. Although deviations could invalidate the Profile Claim, such deviations may be reasonable and unavoidable, and the radiologist or supervising physician is expected to do so when required by the best interest of the patient or research subject. How study sponsors and others decide to handle deviations for their own purposes is entirely up to them.

## 3.1. Pre-delivery

This activity describes calibrations, phantom imaging, performance assessments or validations prior to delivery of SPECT imaging equipment to a site (e.g. performed at the factory) that are necessary to reliably meet the Profile Claim.

#### 3.1.1 DISCUSSION

The Acquisition Device should be held to the same standard whether it is a mobile unit or a fixed installation; a mobile gamma camera may require additional calibration to achieve proper performance.

#### 3.1.2 SPECIFICATION

260

255

Parameter	Actor	Requirement
Release Testing	Acquisition Device	Shall pass all manufacturing in-process and release testing criteria
		Shall encode SPECT raw data in the DICOM Nuclear Medicine Image Storage SOP Class.
File Format	Acquisition Device	Any CT data (used for image correction) should be encoded in CT or Enhanced CT Image Storage SOP Class.
	Reconstruction Software	Shall encode SPECT reconstructed data in the DICOM Nuclear Medicine Image Storage SOP Class.
	Image Analysis Tool	Shall support the DICOM NM Image SOP Class.

## **3.2 Acceptance Tests**

#### 3.2.1 DISCUSSION

Acceptance tests are performed on systems when they are installed in order to 1) ensure that they meet the performance criteria set forth in the purchasing process, and 2) establish a baseline for evaluation of performance over time. Thereafter, the performance tests described in Section 3.3 should be performed at the interval prescribed, or after any major repair. At the very least, acceptance tests should include the intrinsic uniformity, system uniformity, planar spatial resolution, and center of rotation tests described in Section 3.3, although they will typically be more substantive than this.

270 A number of documents (for example, see those produced by the ACR and the IAEA listed in the Reference section) give specific guidance as to how to conduct acceptance testing.

A qualified medical physicist should perform the tests. Alternatively, the tests may be performed by properly trained individuals approved by the medical physicist. The test results should be reviewed by the qualified medical physicist and properly documented.

the qualified medical physicist and properly documented.

## 3.3. Periodic QA

This activity describes calibrations, phantom imaging, performance assessments or validations performed periodically at the site, but not directly associated with a specific subject, that are necessary to reliably meet the Profile Claim.

280

3.3.1 DISCUSSION

A number of documents from several authoritative bodies (e.g., ACR, IAEA, AAPM, NEMA, IPEM, IEC) have been produced that give specific guidance as to how to conduct the tests described below. The list represents a minimum of set of performance measures that should be monitored on a regular basis.

285 Manufacturers' recommendations and institutional policy may require additional tests or that they be performed at shorter intervals.

A qualified medical physicist should perform these tests. Alternatively, the tests may be performed by properly trained individuals, such as a nuclear medicine technologist, who has been authorized by a

290 supervising medical physicist. The test results must be reviewed by the qualified medical physicist and properly documented.

Note that some specifications that follow come from IAEA Human Health Series 6.

Parameter	Actor	Requirement
Phantom tests: Frequency	Physicist	Shall perform and document results of all tests at the required frequency, no less than quarterly, and always after scanner upgrades, and repairs or recalibration of the gamma camera motions and/or detectors
Intrinsic Uniformity	Physicist	Shall confirm quarterly that the intrinsic uniformity from a I-123 point source is comparable with that measured at acceptance testing and within 4% in the UFOV. See 4.1 Assessment Procedure: Intrinsic Uniformity
System Uniformity	Physicist	Shall confirm daily that the system uniformity from a Tc-99m or Co-57 source is comparable with that measured at acceptance testing and within 4% in the UFOV. See 4.2 Assessment Procedure: System Uniformity
Planar Spatial Resolution	Physicist	Shall confirm semiannually that the planar FWHM spatial resolution from the collimators used for Ioflupane imaging is less than 8mm. Fanbeam collimators shall be capable of achieving an equivalent spatial resolution. See 4.3 Assessment Procedure: Planar Spatial Resolution.

#### 295 <u>3.3.2 SPECIFICATION</u>

Center of Rotation (COR)	Physicist	<ul> <li>Shall confirm the mean value of the COR offset does not exceed 1/2 pixel (typically 2 mm) when measured at the center and edges of the FOV.</li> <li>Shall confirm the position of Y=0 axis and the Y gain are the same for all heads in a multi-head system.</li> <li>See 4.4 Assessment Procedure: Center of Rotation</li> </ul>
Tomographic Uniformity	Physicist	Shall confirm the use of appropriate attenuation correction by visually confirming a flat profile through the center of the phantom on several transaxial slices. See 4.5 Assessment Procedure: Tomographic Uniformity
Suitability for basal ganglia imaging	Physicist	<ul> <li>Shall confirm that the caudate and putamen are clearly visualized and that the image does not contain any artefacts.</li> <li>Shall confirm that the estimated wCV of SBR is below 11%</li> <li>Shall confirm that the wCV of Caudate:Putamen ratio is less than 6%</li> <li>See 4.6 Assessment Procedure: Suitability for Basal Ganglia Imaging</li> </ul>
Voxel Noise	Physicist	Should confirm quarterly that the voxel noise in the reference region/background compartment should be below 15%. See 4.7 Assessment Procedure: Voxel Noise in the Reference/Background Compartment
Photon Energy Analyzer	Physicist	Shall confirm (typically daily) that the accuracy of the photon energy analyzer is within manufacturer specifications.
CT Attenuation map registration	Physicist	Shall confirm that the attenuation maps are registered to the SPECT images within the manufacturer specifications.

## 3.4. Subject Selection

This activity describes criteria and procedures related to the selection of appropriate imaging subjects that are necessary to reliably meet the Profile Claim.

#### 300 <u>3.4.1 DISCUSSION</u>

The study is contraindicated in patients with allergies or hypersensitivity reactions to ioflupane, the excipients in the formulation, or iodine, as about 120 mg of Iodine in the form of potassium iodide should be administered by mouth 0.5 to 2 hours prior to the intravenous administration of the <sup>123</sup> lioflupane formulation to minimize thyroid exposure to any free l-123.

305 A urine or serum pregnancy test should be performed prior to the procedure in women of childbearing potential. Radiation exposure makes the procedures relatively contraindicated in subjects who are pregnant. Subjects who are breast-feeding at the time of the examination are advised to stop and discard all breast milk for about one week, after which they may resume.

The study is not approved by health authorities for use in children who might have juvenile forms of Parkinson's disease. While it is known that the product, or similar products, have been approved for research studies in children, this profile is limited to adults with typical basal ganglia size and morphology.

The study is indicated in patients who present with signs and symptoms that are consistent with, but not definitively diagnostic of, Parkinson's disease (PD), and sometimes for confirming a presynaptic

315 dopamine deficit in patients who are entering a clinical trial. Its U.S. regulatory approval is limited to use as a "visual adjunct imaging agent to aid in the differentiation between essential tremor and parkinsonian syndromes." Parkinsonian syndromes include Idiopathic Parkinson's disease (PD), multiple system atrophy (MSA), progressive supranuclear palsy (PSP), and other conditions. Ioflupane is not qualified by national regulatory authorities to distinguish among these conditions.

320	3.4.2 SPECIFICATION

Parameter	Actor	Requirement
	Clinician	For the cross sectional claim, shall establish a differential diagnosis that includes Parkinson's disease versus other causes of parkinsonism, such as essential tremor.
Subject Selection		For the longitudinal claim, shall refer eligible subjects
		Shall take a history of allergies to iodine; Shall perform a pregnancy test in women of childbearing potential

## 3.5. Subject Handling

This activity describes details of handling imaging subjects that are necessary to reliably meet the Profile Claim, specifically with regard to preparation, injection, SPECT scan acquisition, follow up instructions, and other logistics occurring on the scanning day.

#### 3.5.1 DISCUSSION

All procedures should conform to good clinical practices regarding the provision of information to the patient about the risks, benefits, logistics, and reasonable expectations concerning the imaging activities.

No special preparation is required of the patient regarding diet or fasting prior to the procedure. On the scan day the patient should be questioned regarding iodine allergies prior to the administration of nonradioactive potassium iodide. Additional queries should be made about any thyroid disease or

335 surgeries. If the patient has had a thyroid ablative procedure, complete thyroidectomy or otherwise receives exogenous thyroid hormone replacement, it may not be necessary to perform thyroid blockade.

Nonradioactive potassium iodide (100-120 mg) is provided by mouth 30-60 min before anticipated injection of ioflupane. Uptake of the potassium iodide is rapid with some absorption through the gastric mucosa. It is common for patients to describe metallic taste following administration of the thyroid

340 blockade. For patients with iodine allergies potassium perchlorate (400-1000 mg) p.o. has been used, or alternatively, no blockade is performed. Note the low mass dose of iodine contained in radioactive ioflupane does not trigger hypersensitivity reactions in patients with iodine allergies.

Preparation for ioflupane injection involves establishing an intravenous line, usually with the small gauge needle or catheter and confirming patency. Injection of 3-5 mCi of I-123 ioflupane is performed as a bonus over 5 to 20 seconds followed by saline flush of at least 20 mL. There are no specific product guidelines for altering the dose in the context of renal or hepatic impairment. It is not necessary to

- maintain the patient in a special environment to minimize sensory stimulation during the brain uptake phase. Imaging commences 4 h ± 15 min post injection when a secular equilibrium of washout from the basal ganglia and reference region has occurred. Imaging earlier than four hours underestimates specific
   binding ratios in some individuals.
- After 3.5 hours following the ioflupane injection the patient is invited to empty their bladder then positioned in the camera. For most SPECT systems a head holder is required to allow the imaging heads to come within a maximum 15 cm radius. It is important that the patient be comfortable from the outset as they will be in the camera for 30 to 45 minutes. Stress on the lumbar spine may be reduced by
  providing support under the patient's knees. The head may be gently restrained within the head holder to minimize movement. In addition, instructions highlighting the importance of remaining still should be given several times. During the scan acquisition there should be a low level of stimulation in the room (lights dim, no conversational banter, etc.) to minimize motion.

## 3.5.2 SPECIFICATION

360

Parameter	Actor	Requirement
	Nuclear pharmacy, technologist	Shall provide a system that is capable of receiving, dispensing and administering non-radioactive potassium iodide and <sup>123</sup> I ioflupane.
		Shall perform a formal "time out" identification procedure;
Pre-injection	Health care provider (nurse, physician, or technologist)	Shall administer about 120 mg of Iodine in the form of Lugol's solution or supersaturated potassium iodide (SSKI) at least 60 minutes prior to administration of ioflupane, and monitor subjects for adverse events and allergic reactions, such as nausea, vomiting, stomach ache, diarrhea, metallic taste in the mouth, fever, headache, runny nose, or sneezing.
		Shall establish an intravenous line and prove its patency by showing the rate of a saline drip can be easily altered with an inclined roller.
		Shall ensure the subject voids prior to placement on the table
Post-injection	Technologist	Shall place the subject on the table in such a way that maximizes comfort, minimizes the risk of motion, and positions the basal ganglia as close to the center of the field of view as feasible.

SPECT do	pamine trans	porters	(continued)	)
0 0. 0.0				

Parameter	Actor	Requirement
		Shall select the proper acquisition protocol of 123I ioflupane
		Shall begin image acquisition at 4 hours +/- 15 minutes post intravenous administration of ioflupane
Head Holder	0	Shall use an off-the-bed head holder (with appropriate cushioning) to achieve an acquisition radius of 12-15cm.

## 3.6. Image Data Acquisition

This activity describes details of the data acquisition process that are necessary to reliably meet the Profile Claim.

#### 365 <u>3.6.1 DISCUSSION</u>

We define acquisition mode parameters as those that are specified by the Technologist at the start of the actual SPECT/CT scan. These parameters do not include aspects of the acquisition that occur earlier (e.g., injected activity) or later (e.g., reconstruction parameters) in the overall scan process.

#### **SPECT Acquisition**

- 370 The SPECT acquisition is performed on a properly calibrated SPECT/CT or stand-alone SPECT system with at least two imaging heads fitted with collimators as described in the specifications below. Single headed SPECT systems are not recommended. Parallel-beam and fan beam collimators with manufacturer specified (or measured according to NEMA standards) planar system resolution of < 8 mm FWHM (in 'air' at 10 cm distance) typically meets the resolution requirement in the table below. These
- 375 are typically referred to as Low Energy High Resolution (LEHR), Low Energy Ultra-High Resolution (LEUHR) collimators. Some (typical low-energy) collimators allow too much septal penetration of the high-energy emissions of I– 123, resulting in ring artifacts that may affect quantitation. ME collimators, which reduce septal penetration, may be insufficient in terms of the resolution requirement. If available, collimators designed specifically for <sup>123</sup>I brain SPECT should be used.
- 380

390

Once the patient is placed on the imaging table it is important to have the radius of the rotation as small as possible. This may be particularly challenging in patients with degenerative spine disease or other orthopedic problems affecting posture. The acquisition is adequately performed in step and shoot mode with angular sampling every 3 degrees collecting photopeak counts (159 keV +/- 10%) into a 128 x 128

385 matrix. Acquisitions are obtained for a minimum of 1.5 million counts. Total time to collect at least 1.5 million counts can be calculated by viewing the count rate in the anterior view. Time per view is total time divided by number of projections.

There are no data that support a rationale for variable SPECT acquisition mode parameters, specifically the acquisition time depending on subject weight and or amount of injected I-123. The acquisition can also be performed as a dynamic SPECT (for example, six 5 minute frames) to better assess motion. Only

those frames where significant motion is not evident are summed for the reconstruction.

## 3.6.2 SPECIFICATION

Parameter	Actor	Requirement	DICOM Tag
Imaging device	Technologist	The acquisition device <u>shall be selected</u> to produce comparable results regardless of the scanner make and model. <b>Camera:</b> Multi detector SPECT or SPECT/CT cameras shall be used.	
	Technologist	Shall be certified by local authorities to operate the instrument in compliance with this profile.	
Collimator		Shall use a collimator that provides planar system resolution of < 8 mm FWHM (in 'air' at 10 cm distance) for Tc-99m (or equivalent for fanbeam collimators).	

Parameter	Actor	Requirement	DICOM Tag
SPECT Acquisition mode	Technologist	The key SPECT acquisition mode parameters <u>shall</u> <u>be specified</u> in a manner that is expected to produce comparable results regardless of the scanner make and model. The key parameters are: <b>Rotational radius</b> : shall be fixed at 11 – 15 cm (circular orbit) or smallest possible. An off the table head rest is usually needed to achieve this. <b>Matrix and pixel size</b> : A matrix size and zoom factor that gives a pixel size of one-third to one- half the expected spatial resolution shall be used. Typically, a 128 x 128 matrix and pixel size of no larger than 4 mm. <b>Angular sampling:</b> 360 degree coverage of the head with angular sampling of not less than 120 views shall be used (<= 3 degree increments). Step-and-shoot is typically used, but continuous mode can be used to provide shorter total scan time. <b>Total counts:</b> The scan time shall be adjusted to obtain > 1.5 million total counts detected in the photopeak window. Typically, this requires a 25 – 45 min scan. <b>Energy windows:</b> The photopeak window shall be set at 159 keV +- 10% (143 – 175 keV) or as recommended by the system manufacturer. If triple energy-window (TEW) based scatter correction is to be used, two additional narrow	

Parameter	Actor	Requirement	DICOM Tag
		windows (typically 7%) adjacent to the photopeak or as recommended by the system manufacturer shall be used.	
	-	The technologist shall set up the acquisition, acquire the data, and store the data.	

## **CT Acquisition**

For the CT component of the SPECT/CT scan, this Profile only addresses the aspects related to the quantitative accuracy of the SPECT image. The focus is on attenuation correction and anatomical
 localization only. This profile does not describe a diagnostic CT scan. When CT is used for attenuation correction only, the CT can be performed with 5 – 10 mAs. When used for anatomic localization, the CT can be performed with 110-130 kVp, pitch 0.8-1.5). The CT acquisition parameters should be selected based on Image Wisely guidelines (see <a href="http://www.imagewisely.org/imaging-modalities/nuclear-medicine/articles/ct-protocol-selection">http://www.imagewisely.org/imaging-modalities/nuclear-medicine/articles/ct-protocol-selection</a> and availability on the scanner.

Parameter	Actor	Requirement	DICOM Tag
CT Acquisition mode	Technologist	<ul> <li>The key CT acquisition mode parameters (kVp, mAs, pitch, and collimation) shall be specified in a manner that is expected to produce comparable results regardless of the scanner make and model, and with the lowest radiation doses consistent for the role of the CT scan: correction for attenuation and for localization.</li> <li>The CT acquisition mode shall utilize the protocol that delivers the lowest possible amount of radiation dose to the subject (e.g. a relatively low dose protocol) that retains the quantitative accuracy of corrections for attenuation.</li> </ul>	
	Technologist	The key CT acquisition mode parameters (kVp, mAs, pitch, and collimation) shall be set as specified by study protocol and used consistently for all subject scans.	

Parameter	Actor	Requirement	DICOM Tag
CI Technique:	Medical Physicist	A team comprising a Technologist / Physician / Medical Physicist shall ensure that CT techniques protocols are designed such that dose exposure is the lowest radiation dose necessary to achieve the objective.	

SPECT dopamine transporters (continued)

Parameter	Actor	Requirement	DICOM Tag
		Protocols defined by Image Gently and Image Wisely should be used where feasible. The protocol shall be recorded and documented.	
	Technologist	The technologist shall ensure that the CT dose conforms to the dose prescribed by the supervising physician or protocol.	

## 3.7. Image Data Reconstruction

410 This activity describes criteria and procedures related to producing images from the acquired data that are necessary to reliably meet the Profile Claim.

#### 3.7.1 DISCUSSION

415

Reconstruction is performed on the projection data following a quality control check of the sinogram to assess for any motion and potential artifacts (see Section 3.8). Goal of the reconstruction is to provide a well-delineated basal ganglia, which allows regional sampling of the caudate and putamen. Alterations in dopamine transporter density are asymmetric with regard to the caudate and putamen as well as the

in dopamine transporter density are asymmetric with regard to the caudate and putamen as well as the left and the right side of the brain. The optimal reconstruction, correction, and filtration method depends on the image analysis method used (see Section 3.10).

Images can be reconstructed using either iterative (e.g., OSEM or conjugate gradient) or analytic
 reconstruction methods provided appropriate compensations are included, as described below. Iterative methods are typically preferred as they allow for more accurate and complete compensation.

Reconstructed images must be corrected for attenuation. The attenuation map used in the correction can either be measured with a transmission scan, e.g., x-ray CT (preferred), or estimated from boundaries of the head, (e.g. using ellipses). The attenuation correction can be implemented either

- 425 using iterative (e.g., OSEM), analytical (e.g., Tretiak-Metz), or approximate (e.g., Chang 0) algorithms. Approximate and analytic attenuation correction methods typically use an estimated map and assume uniform attenuation. The use of measured attenuation maps and iterative reconstruction is preferred. Measured attenuation maps obtained from CT images should have the attenuation values translated so that they are appropriate for 159 keV and be registered to the emission images with an accuracy of
- 430 better than 2 mm.

Correction for scatter is preferred, and should take into account down scatter from high energy photopeaks. Scatter correction can be implemented using energy-window-based scatter estimates (e.g., the TEW method) or scatter modeling methods (e.g., ESSE [Frey, 1996] or Monte Carlo-based [Dewaraja 2006, Beekman 2002]). For filtered backprojection-based reconstruction the scatter estimate is typically

435 subtracted from the projection data. For iterative reconstruction, the scatter compensation should be incorporated into the reconstruction algorithm in order to obtain the best noise properties.

For the whole striatum VOI image analysis method (see Section 3.10), collimator-detector-response (CDR) compensation, a large number of iterations (typically > 100 image updates for OSEM), and little or no post-reconstruction filtering is recommended in order to reduce partial volume effects. Explicit

440 partial volume compensation may be useful for this the whole striatum VOI method. For the small VOI method, CDR compensation may lead to ringing artifacts that complicate quantification and thus is not recommended. A smaller number of iterations and some post-reconstruction low-pass filtering can be useful to help control noise and its effects on the regional activity estimates.

If pre-or post-reconstruction low-pass filtering is applied to the images it is important that the filter be linear across the count ranges. It is desirable that reconstructed images be saved in such a way as to preserve as much dynamic range (numeric precision) as possible and avoid truncation of voxel values. Storing scale factors needed to convert the images to activity concentration units is encouraged.

A core lab and/or common reconstruction methods will provide lower variability and may offer benefits in certain scenarios[Buchert, et al, 2016].

## 450 <u>3.7.2 SPECIFICATION</u>

Parameter	Actor	Requirement
SPECT Image Reconstruction	Technologist	The key SPECT reconstruction parameters (algorithm, iterations, smoothing, field of view, voxel size) shall be specified in a manner that is expected to produce comparable results regardless of the scanner make and model. The key SPECT image reconstruction parameters shall be specified according to pre-determined harmonization parameters.
	Technologist	The key SPECT reconstruction parameters (algorithm, iterations, smoothing, field of view, voxel size) shall be followed and set as specified in order to produce comparable results regardless of the scanner make and model.
SPECT Matrix/Voxel size	Technologist	The Technologist shall perform the image reconstruction such that the matrix, slice thickness, and reconstruction zoom shall yield a voxel size of < 4 mm (same as projection bin size) in all three dimensions, although not necessarily isotropic. The final size shall not be achieved by re-binning, etc., of the reconstructed images.
Correction: Attenuation	Technologist	Uniform or non-uniform attenuation correction shall be included in the reconstruction. For uniform correction a narrow beam attenuation coefficient of 0.148 cm <sup>-1</sup> shall be used when scatter correction is included while a broad beam attenuation coefficient of 0.11 cm <sup>-1</sup> shall be used when scatter correction is not included. For non-uniform attenuation correction the attenuation map shall be obtained by a transmission measurement or x-ray CT (preferred).
Estimated Attenuation Map (if used)	Technologist	Shall be defined so that it conforms to the outline of the head as closely as possible.
Correction: Scatter	Technologist	Scatter correction shall be used when possible. TEW or equivalent is recommended.
Reconstructed image	Technologist	<ul> <li>Shall be reconstructed in such a way as to compensate for attenuation and scatter.</li> <li>Optimal reconstruction depends on the image analysis method used (see Section 3.10).</li> <li>Whole striatum VOI method: the reconstruction shall be implemented to reduce partial volume effects, e.g., using CDR and partial volume compensation. Controlling voxel-level noise is less important, so post-reconstruction filtering is not recommended, though may be used for visual interpretation.</li> <li>Small VOI method: the reconstruction shall be implemented to</li> </ul>

Parameter	Actor	Requirement	
		control the effects of voxel-level artifacts such as noise spikes and ringing, including the use of 3-dimensional low-pass post- reconstruction filtering (with 8 – 10 mm FWHM).	
		The reconstructed image shall have sufficient spatial resolution to allow reliable independent estimates of the SBR in the Caudate and Putamen.	
Stored Reconstructed Image	Camera Manufacturer	Reconstructed images shall be stored in such a way as to preserve the image dynamic range.	

## 3.8. Image QA/QC

This activity describes criteria and evaluations of the images that are necessary to reliably meet the 455 Profile Claim.

#### 3.8.1 DISCUSSION

465

Visual image assessment is performed to assess the adequacy of the acquisition for a quantitative endpoint and to ensure that there are no acquisition artefacts. Checks for the integrity of the reconstruction include well-defined basal ganglia, nonspecific cortical uptake with sharp boundaries of the cortical edge, and well defined scale uptake. Furthermore an assessment of motion and image poise

460 the cortical edge, and well-defined scalp uptake. Furthermore an assessment of motion and image noise is essential to ensure that the images can meet the profile claim.

To assess motion, after acquisition and before reconstruction a review of sinograms and projection data in cine mode shall be used for an initial determination of scan quality, patient motion, and artifacts. A sinogram review will reveal transverse patient motion as discontinuities in the sinusoidal form of shapes included within the image, while a review of cine projection data can help show head a raising/lowering of the chin, or indeed the complete head following each projection. Cine review of planar images will show up patient motion along the axis of rotation. Motion can also be assessed following reconstruction. Signs of motion include blurring of the boundaries between high uptake areas in the basal ganglia and adjacent regions, e.g. the heads of the caudate may appear too close.

- 470 Where CT attenuation correction is to be performed, it is essential that there has been no movement between the emission and CT acquisitions. If motion has occurred between these two acquisitions, the attenuation correction will be compromised. Some software allows retrospective alignment of the CT and emission data, and this should be used if available. If such software is not available, attenuation correction should not be applied, or a repeat acquisition should be considered.
- 475 Where Chang attenuation correction is performed, it is important that the boundaries defining the object are accurately defined to ensure appropriate correction.

If 1.5 million counts are acquired in the SPECT acquisition, noise levels in the data will be acceptable. If there is extravasation of the Ioflupane, an excessive time per projection will be selected during the acquisition setup (see Section 3.6). Other issues which may lead to noisy data include the incorrect

480 measurement of injected activity, poor or variable peaking during the acquisition, or the incorrect selection of an energy window. Once more many of these issues should be picked up during the acquisition setup where an excessive time per projection would be calculated, although energy peaking that varies during the data acquisition process would not be picked up until after data acquisition. If noisy data is suspected, reconstructed slices should be summed and the total number of reconstructed 485 counts calculated to ensure that the 1.5 million count target has been met.

#### 3.8.2A SPECIFICATION QC

Parameter	Actor	Specification
Artifact assessment	Technologist	Shall ensure that the data is not confounded by ring artifacts, artifacts related to too large a radius for COR (i.e., should be <15 cm, or edge artifacts
Patient Motion	Technologist	Shall assess projection and reconstructed emission data for patient motion.
Mis-registration of SPECT and CT for attenuation correction	Technologist	Shall ensure that the attenuation map is visually registered to the CT map within one reconstructed voxel dimension.
Definition of Chang AC boundaries	Technologist	Shall ensure that boundaries used in the Chang attenuation correction process are accurately defined.
Image Noise	Technologist	Shall ensure that 1.5 million counts have been acquired to achieve an acceptable level of image noise.

#### 3.8.2B SPECIFICATION QA

The normative list below is based on the recommendations from several national and international guidance documents.

Parameter	Actor	Specification	
Phantom tests: Frequency	Imaging Site	Shall perform and document results of all tests no less than quarterly, and always after scanner upgrades, and repairs or recalibration of the gamma camera motions and/or detectors	
Phantom tests: Planar Uniformity	Imaging Site	Shall ensure uniformity of response to a uniform flux of radiation. An I-123 point source shall be measured intrinsically every quarter. On a daily basis planar uniformity with collimators used for I-123 imaging should be performed using a Tc-99m or Co-57 source. See also Section 3.3.2	
System Spatial Resolution	Physicist	Shall test the resolution of the system in terms of the FWHM of its point spread function. Test should be conducted semiannually with the collimators routinely used with <sup>123</sup> I ioflupane studies. The result of the test should be less than 8 mm at 10 cm. See also Section 3.3.2	

SPEC	Γ dopamine transporters	(continued)

Phantom tests: transaxial uniformity measurement	Imaging Site	Shall use a uniform cylinder filled with I-123, to obtain a within slice variability of less than 5%.
Phantom tests: suitability for basal ganglia imaging	Imaging Site	Shall employ an anthropomorphic phantom with basal ganglia and reference region background compartments filled at a homogeneous striatal ratio of 4.5:1, to distinguish the caudate nuclei and putaminal, and also with a caudate/putamen gradient of 4.5:1 caudate, 2.25:1 putamen to assess systems ability to determine an uptake gradient across the striata. This phantom should also be used to check for adequacy of attenuation correction.
Phantom test:	Imaging Site	Shall assess voxel noise in the reference region/background compartment. The COV of the volume of interest thus determined should be recorded and should be below 15%.
Phantom test: data acquisition	Imaging Site	Shall acquire according to Section 3.6
Phantom test: data reconstruction	Imaging Site	Shall reconstruct according to Section 3.7
Phantom test: data analysis	Imaging Site	Shall ensure noise is less than specified above.

### 3.9. Image Distribution

This activity describes criteria and procedures related to distributing images that are necessary to reliably meet the Profile Claim.

#### 3.9.1 DISCUSSION

495 Discussions of archiving and distributing SPECT data often mention 'raw data'. This is an ambiguous term as it can refer to: scanner raw data (i.e., sinograms) or image raw data. To avoid confusion, the term raw data should not be used without making it clear which form is under discussion.

Scanner raw data include the sinograms as acquired from the SPECT scanner, i.e., a list of planar
 projection images, one image for each acquired angle and energy window. This is always a single DICOM file containing projections images grouped by acquisition energy window. These projections can be analyzed by the Image Data Reconstruction Software.

*Image raw data* is the image data exactly as produced by the reconstruction process by the Image Data Reconstruction Software, i.e., a stack of DICOM slices/files constituting a SPECT image volume with no

505 processing other than that occurring during image reconstruction. This is always a stack of DICOM slices/files constituting a SPECT image volume that can be analyzed on one or more of the following: SPECT scanner console, SPECT image display workstation, PACS system, etc. **Post-processed image data** are images that have been transformed after reconstruction in some

manner, including but not limited to: smoothing, image zoom, rotation/translation, resampling, spatial

- 510 normalization, interpolation, slice averaging, MIP, etc. This is typically a stack of DICOM slices/files constituting a SPECT image volume that can still be analyzed on one or more of the following: SPECT scanner console, SPECT image display workstation, PACS system, etc.
- For distributing and archiving at the local site or imaging core lab (if relevant), the most important data are the reconstructed images, i.e., the image raw data, and post processed image data including averaged images if any. In the unlikely event that the scanner raw data (which should be archived by the local site) is required for later reprocessing; this should be made clear in the protocol. Should scanner raw data be archived, all information needed for proper reconstruction and attenuation correction should be kept in DICOM files.

#### 3.9.2 SPECIFICATION

Parameter	Actor	Requirement
Image Distribution	Technologist	<ul> <li>Shall ensure the original projections (sinogram) images (scanner raw data), are always archived at the local site.</li> <li>The reconstructed SPECT images (image raw data), along with all required corrections, and CT images shall always be archived at the local site.</li> <li>If processed SPECT images are required, they shall be archived as separate secondary datasets.</li> <li>If scanner raw data need to be archived for future reprocessing, this should be defined prospectively in the Protocol.</li> </ul>

#### 525 3.10. Image Analysis

This activity describes criteria and procedures related to producing quantitative measurements from the images that are necessary to reliably meet the Profile Claim.

#### 3.10.1 DISCUSSION

The Image Analyst using computer workstation analysis tools shall perform the specified measurements.
The main quantitative data analysis task is to determine the Specific Binding Ratios (SBR) of Ioflupane (DaTscan™, GE Healthcare, Arlington Heights, IL) for the right and left caudate and putamen. The derived results are then compared to an age-normalized database to provide a reference for the SBR versus agematched healthy participants. The profile describes the data analysis methodology.

Quantitative Specific Binding Ratio (SBR) of Ioflupane will be based upon patient SBR and compared to an
 age normalized database (or striatal phantom or digital reference object as the case may be). Qualified systems will be able to achieve a SBR within a certain range (i.e., ±15% of reference value) for quantitative imaging of I-123 Ioflupane for the basal ganglia phantom (described in this profile). Further, the coefficient of repeatability (RC) should be <15% for repeat studies of VOIs that are the size of the whole striatum. The profile seeks to provide the methodology for data analysis and also for qualification of systems and processing for I-123 Ioflupane data analysis.</li>

Input Data:

The output images from Image Reconstruction are considered the input for Image Analysis. Once stored on the analysis workstation the image data will be processed for region of interest image analysis as described below. The original input data will be maintained as a separate file and will be stored along with the processed data for image analysis. In addition to output images from Image Reconstruction, physical phantom and digital reference object images may also be used as input for Image Analysis to validate the Image Analysis and workstation tools. Two types of digital reference objects will be considered. The first will represent the actual I-123 Ioflupane tracer distribution without any of the effects associated with the

550 data acquisition and image reconstruction process. The second object will be a digital representation of first object including all physical effects and image reconstruction. Both digital reference objects will have

known SBR's that can be used to assess the data analysis tools and workstation. The SBR for one half of the DRO will represent healthy control and the other side a patient with Parkinson's disease. The true caudate to reference region (background) SBR will be the same for both sides and set to 4.5. The Caudate

555 to reference region SBR after image reconstruction is 2.5. The true SBR for the healthy putamen will be 4.5 and 2.25 for the diseased putamen. The physical phantom will be the commercially available striatal Head Phantom. The caudate, putamen and reference/background regions will be filled with activity concentrations that mimic the digital reference object (i.e., actual tracer distribution).

Methods to be Used:

560 Uptake in the striatum (i.e., caudate, anterior putamen and posterior putamen) and reference region (e.g., cerebellum or occipital region) is characterized by defining a volume-of-interest (VOI). The measurand is the specific binding ratio and is determined from the following equation:

 $\frac{striatum_{VOI} - backgrnd_{VOI}}{backgrnd_{VOI}}$  (eq 1)

where the reference/background (backgrnd)  $_{VOI}$  counts are normalized to the same VOI volume as the

565 striatal VOI (i.e., caudate or anterior putamen or posterior putamen).

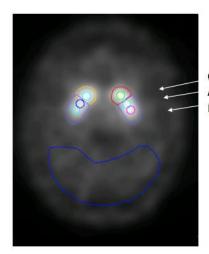

Volumes of interests will be drawn on preprocessed images as described below.

Two volume of interest analysis strategies are described. The first method is referred to as the Small VOI approach. The second method is referred to as the whole striatum VOI approach.

The small VOI approach is described as follows. On spatial normalized SPECT image volumes the transaxial

- 570 slice with the highest striatal uptake plus and minus up to two adjacent slices spanning an axial extent of 2 cm or less are averaged to generate a single slice image. VOIs are then placed on the left and right caudate, the left and right putamen, and the occipital cortex (reference tissue), as
- 575 shown in Figure 3.10.1. It should be clear which values belong to which striatal structures. MRI anatomical images can be used for VOI drawing if they exist. VOIs maybe placed according to VOI template or using semi-automated or automated placement tools. Count densities for each region
- 580 are extracted and used to calculate specific binding ratios (SBRs) for each of the striatal regions. SBR is calculated as ((target region – reference region)/reference region), as described above in eq 1.

The whole striatum VOI approach is similar to the Small VOI

Caudate Ant putamen Post putamen

Figure 3.10.1. Illustration of Small VOI placement on summed slice image.

585 approach but uses larger volumes of interest (VOIs) and does not separate the putamen into two regions. The whole striatum VOI approach is implemented in many commercial software packages. The reconstructed image is spatially normalized to a SPECT template. Volumes of interest sampling most of the right and left caudate and putamen are drawn on the image as illustrated in Figure. 3.10.2. Reference/Background VOIs are drawn on the occipital cortex, as shown. VOIs

590 can be systematically placed or semi-automatically or automatically defined over the caudate nucleus and

putamen to assess specific tracer binding and over the occipital cortex to assess non-specific binding. The striatal specific binding ratios are calculated using equation 1.

595 Required characteristics of resulting data:

The specific trial protocol shall prospectively define the SBR parameter that is required for the striatum and the caudate and putamen, specifically. Some studies may also compare different metrics (e.g., right to left asymmetry or caudate to putamen 600 ratio) and will require recording multiple parameters. SBR measures (and the analysis tools used to obtain them, including software version) shall be used consistently across all subjects and across all sequential SBR measurements.

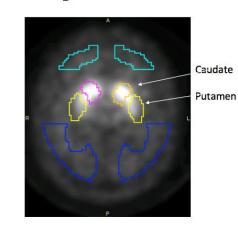

Figure. 3.10.2. Illustration of Large VOI placement on summed image.

SBR's are intended as a measure of relative uptake and in that sense, can be regarded as dimensionless (unitless)

It should be clear which values belong to which structures (e.g., the whole striatum, left – right caudate, left – right putamen). This can be done by capturing DICOM coordinates along with the SBR or secondary screen captures of the VOI for identification. It should be reported what reference region was used for normalization (e.g., occipital cortex or cerebellum).

610 The analysis software should generate a report.

**In the USA**, under the Centers for Medicare & Medicaid Services' Medicare Improvements for Patients and Providers Act of 2008 (MIPPA), the American College of Radiology (ACR) is required to validate compliance with accreditation requirements on advanced diagnostic imaging service facilities. Facilities should refer to the tool kit available on the ACR website at the bottom of the Breast MRI, CT, MRI,

615 Nuclear Medicine and PET Accreditation Program pages located at <u>http://www.acraccreditation.org/modalities/mri</u>

These documents will help facilities gather and organize information for periodic the site surveys.

Some of the most common items that are not found during a survey are the following:

- Policies for primary source verification, verifying that personnel are not included on the Office of Inspector General's exclusion list and a consumer complaint notice that gives the patients contact information for the ACR (one can be found on our website at <u>http://www.acr.org/~/media/ACR/Documents/Accreditation/PatientNotice.pdf</u>.
  - Documentation of initial qualifications, continued education and continued experience for the interpreting physician and medical physicist. Self-documentation is not acceptable.

**In Japan**, the European Union, and other regions, professional health care providers should meet, and maintain, standards set by their local regulatory authorities for the practice of medicine with unsealed radioactive material.

Visual image assessment is performed to assess he adequacy of the acquisition for a quantitative

630 endpoint. Checks for the integrity of the reconstruction include well-defined basal ganglia, nonspecific cortical uptake with sharp boundaries of the cortical edge, and well-defined scalp uptake. Signs of motion include blurring of the boundaries between high uptake areas in the basal ganglia and adjacent regions, e.g. the heads of the caudate may appear too close.

Assessment of the quality of the subsequent quantitative analysis is critical, with particular focus on the accurate anatomic placing of the regions of interest.

#### 3.10.2 SPECIFICATION

Parameter	Actor	Requirement
Specific Binding Ratio	Image Analyst	Analysis Workstation Shall have a suitable monitor of appropriate size and pixel density for diagnostic viewing of medical images. Shall be placed in a room with in room lighting appropriate for image data analysis and interpretation (i.e., a radiology reading room). Shall have appropriate computation power and memory to carryout VOI data analysis.
		Post processed image for data analysis Shall make sure images for data analysis are reconstructed in accordance with parameters as described in Section 3.7. If needed, image shall be spatially normalized. If using the Small VOI approach, the transaxial slice with the highest striatal uptake plus and minus up to two adjacent slices spanning an axial extent of 2 cm or less shall be averaged to generate a single slice image.
		VOI software analysis tools Shall use analysis workstation tools to place volumes of interest placed on the left and right caudate, the left and right putamen, and the reference tissue. Count densities for each region shall be extracted to calculate SBRs for each of the striatal regions and for the striatum as a whole. VOIs shall be systematically placed by the image analyst or by the image analysis software.
Certify VOI	Qualified professional	Shall either (1) agree with region boundaries, (2) reject boundaries and return for reprocessing, or (3) make revisions "on the fly" as indicated.

## 640 **4. Assessment Procedures**

To conform to this Profile, participating staff and equipment ("Actors") shall support each activity assigned to them.

To support an activity, the actor shall conform to the requirements (indicated by "shall language") listed in the specifications table of the activity subsection in Section 3.

645 Although most of the requirements described in Section 3 can be assessed for conformance by direct observation, some of the performance-oriented requirements cannot, in which case the requirement will reference an assessment procedure in a subsection here in Section 4.

Formal claims of conformance by the organization responsible for an Actor shall be in the form of a published QIBA Conformance Statement. Vendors publishing a QIBA Conformance Statement shall

650 provide a set of "Model-specific Parameters" describing how their product was configured to achieve conformance. Vendors shall also provide access or describe the characteristics of the test set used for conformance testing.

## 4.1 Assessment Procedure: Intrinsic Uniformity

This procedure can be used by a vendor or an imaging site to assess the uniformity of images from an acquisition device detector. Planar Uniformity is assessed in terms of the integral uniformity and 655 differential uniformity of pixel values when imaging a uniform source. Due to the expense of I-123, this assessment is performed less frequently than the System Uniformity assessment (See 4.1b).

Additional guidelines for this procedure are available from authoritative bodies such as IAEA, AAPM, NEMA, IPEM, IEC.

- 660 The assessor shall suspend a small point source of I-123 above the uncollimated gamma camera at a distance of five times the diameter of the crystal. The assessor shall acquire a flood image with count densities of at least 10,000 counts per pixel (about 30 million total counts for a 64x64 matrix). The image should be visually assessed for variations in count density, noting any areas that clearly stand out. The assessor shall measure and record the integral uniformity and differential uniformity as defined in the
- 665 above-mentioned guidelines.

## 4.2 Assessment Procedure: System Uniformity

This procedure can be used by a vendor or an imaging site to assess the uniformity of images from the combined system of a detector and a collimator in an acquisition device. System Uniformity is assessed in terms of the integral uniformity and differential uniformity of pixel values when imaging a uniform

670 source.

> Additional guidelines for this procedure are available from the manufacturer and authoritative bodies such as IAEA, AAPM, NEMA, IPEM, IEC.

The assessor shall prepare a flood source using either Tc-99m or Co-57 following the guidelines recommended by system manufacturers. The assessor shall place the flood source in contact with the

675 face of the collimator that will be used for I-123 imaging and acquire 10 - 30 million total counts. The image should be visually assessed for variations in count density. The assessor shall measure and record the coefficient of variation, integral uniformity and differential uniformity as defined in the abovementioned guidelines.

## 4.3 Assessment Procedure: Planar Spatial Resolution

680 This procedure can be used by a vendor or an imaging site to assess the planar spatial resolution of the acquisition device. Planar Spatial Resolution is assessed in terms of the Full-Width Half-Max (FWHM) of a line spread function.

Additional guidelines for this procedure are available in NEMA NU 1-2012 for measuring system spatial resolution without scatter.

685 The assessor shall fill a capillary tube with an inside diameter < 1 mm with Tc-99m to an active filled length of at least 120mm. The assessor shall position the tube 100mm from the face of the collimator in air and along the axis of measurement. The assessor shall acquire an image, with the collimators routinely used for 123I ioflupane studies, and measure the FWHM of the line spread function as outlined in NEMA NU 1-2012.

#### 4.4 Assessment Procedure: Center of Rotation 690

Center of rotation performance can be assessed by following the NEMA guidelines for measuring system alignment of gamma camera tomographic systems. The mean value of the COR offset should not exceed 1/2 pixel (typically 2 mm) when measured at the center and edges of the FOV. Position of Y=0 axis and the Y gain should be the same for all heads in a multi-head system.

695

700

705

## 4.5 Assessment Procedure: Tomographic Uniformity

As a SPECT technique, loflupane imaging requires correction for photon attenuation within the brain to be accurately quantified. Using either Chang 0 or iterative compensation or estimated or measured attenuation maps, it is important to assess that the correction for attenuation is being applied appropriately. It is also important to assess that center of rotation corrections are fit for purpose. With such potential sources of error, it is important for all trials that transaxial plane uniformity is assessed. This can be achieved by acquiring a high count (~15 million counts) SPECT acquisition of a cylindrical phantom filled with Iodine-123 solution. Following reconstruction with corrections applied for attenuation and possibly scatter, a profile about 3 cm wide should be placed through the center of rotation of the phantom, and the resulting count distribution visually assessed for the appropriateness of CT or calculated attenuation correction. A correctly applied attenuation correction should yield a flat

profile other than image noise.

The performance of the system with such tests may change following any detector changes or
 recalibration, and for SPECT after mechanical changes made to the system and should therefore be checked after such actions have been performed.

## 4.6 Assessment Procedure: Suitability for Basal Ganglia Imaging

- To qualify the SPECT scanner for clinical practice or for a clinical trial, a phantom imaging procedure is
   required. For the specific application described in this document, the commercially-available striatal
   Head Phantom with removal brain shell is to be used for the tests described below. Typically, the
   phantom filled with an activity concentration in the uniform area of the brain shell of approximately 5
   kBq/ml (0.135 uCi/ml), is similar to the expected average normal tissue concentration at the time of
   imaging in an average weight (70-80 kg) subject in combination with the intended I-123 ioflupane
   dosage of up to 185 MBq (5 mCi). However, to speed up the phantom scanning process, increasing the
   activity concentration in the uniform area of the brain shell to 15 kBq/ml (0.405 uCi/ml) is possible,
   without producing any unwanted deadtime effects.
- To characterize system performance, two different scenarios should be created within the striatal
   phantom: one side will represent a healthy subject, while the other will demonstrate dopaminergic
   degeneration typical of Parkinson's disease.

Both striatal compartments on the right side of the phantom should be filled with the same concentration representing a true uptake ratio of 4.5:1. Given that the reference/background
compartment has a value of 15 kBq/ml and on the basis that SBR = (compartment – background) / background, the activity concentration of these striatal compartments will be 82.5 kBq/ml (2.23 uCi/ml). The left striatal compartment will also have a caudate SBR of 4.5:1 and a putamen SBR of 2.25:1. This putaminal ratio of 2.25:1 will require a solution with an activity concentration of 48.75 kBq/ml (1.32)

uCi/ml). Assuming a reference/background compartment volume of 1500 ml, the required concentration
 can be reached by adding 22.5 MBq (0.61 mCi) of I-123 to this volume. The volume of the right striatum and left caudate is 17.4 ml. Creating 20ml of solution to fill these compartments would require 1.65 MBq (44.60 uCi). The left putamen volume is 6 ml. Producing 10ml of filling solution for this compartment would require 0.49 MBq (13.18 uCi). Multiple dilutions will often be necessary to reach accurate values for the striatal dilutions given the issues of radionuclide calibrators in this range. All activities should be measured on a dose calibrator undergoing Quality Control as recommended by, e.g., AAPM, IAEA and with accuracy traceability to NIST or equivalent metrology labs.

Once the phantom is prepared with the above filling ratios, 20 SPECT scans using the imaging/acquisition parameters specified in Section 3.6 should be performed with re-positioning after each scan. Each scan should be set up to achieve ~ 3 million counts total per scan, which typically takes 20 – 30 min per scan. Image reconstruction should be performed as specified in Section 3.7.

All images should be visually assessed to ensure that the caudate and putamen compartments of the phantom are visible, and that there are no artefacts present.

#### 750

The striatal compartments (L and R caudate, L and R putamen) can be segmented on the CT of the SPECT/CT when available or can be defined as specified in Section 3.10. The background should be defined as specified in Section 3.10. Then, for each of the repeat scans the SBR for the striatal compartments should be determined. For conformance testing the within-subject Coefficient of Variation (wCV) of the SBR values should be calculated for each of the striatal regions. The wCV of the SBR is the relative standard deviation (standard deviation of the replicate measurements divided by their mean) estimated from the multiple scans:

 $\% wCV = (\widehat{SD}/\overline{x}) \times 100$ . Estimate the % Repeatability Coefficient as  $\widehat{\% RC} = 2.77 \times \% wCV$ 

#### 760

755

To be 95% confidence that the claims are met (i.e. that the wCV of the SBR is  $\leq$ 15%), the estimated wCV of the SBR must be < 11%. Similarly, the caudate:putamen uptake ratio should be determined for each scan and the wCV should be estimated. The wCV of the caudate:putamen ratio must be < 6% (to be 95% confident that the wCV of caudate:putamen uptake ratio is  $\leq$ 8%).

#### 765

Following reconstruction with corrections applied for attenuation and possibly scatter, a profile about 3 cm wide should be placed through the identified uniform region of the brain background. The count distribution should be visually assessed for the appropriateness of the attenuation correction. A correctly applied attenuation correction should yield a flat profile other than image noise.

#### 770

The phantom scans and performance evaluation should be performed prior to the start of a trial and repeated during the course of the trial as specified by the individual protocol. Any changes to scanner equipment, either hardware or software, should be immediately reported to the trial sponsor and/or imaging CRO and may result in the need for re-qualification prior to imaging additional trial subjects. In

775 particular, it is strongly recommended that subjects in a longitudinal study be scanned on the same SPECT system with the same software version whenever possible. Moreover, image reconstruction methods and settings used for the phantom study should be equal to those specified in the trial protocol or equal to those routinely applied in the local clinical setting.

## 780 4.7 Assessment Procedure: Voxel Noise in the Reference/Background Compartment

Specific Binding Ratio (SBR) calculations involve the regions of interest in the striata and also a region such as the cerebellum or occipital lobe, which acts as a measure of non-specific tracer binding. Noise levels in the non-specific binding region will therefore have an impact on the uncertainty in SBR.

- 785 Image noise levels in this region should be measured using the anthropomorphic striatal phantom of (Section 4.6) with a uniform area to assess image 'noise' by means of the coefficient of variation (COV). The COV is also known as the relative standard deviation (%RSD), which is expressed as a percentage and is defined as COV = (SD / Mean) x 100, for the voxel values within a specified volume of interest (VOI). The phantom should be scanned using the minimal time per bed specified in the trial protocol or
- 790 using the routinely applied time per bed in the local clinical setting. Moreover, image reconstruction methods and settings should equal those specified in the trial protocol or equal those routinely applied in the local clinical setting. A volume of interest (VOI) should be positioned entirely within the phantom's uniform area (the brain compartment), with its size and position chosen to match that used to quantify SBR. The COV of the volume of interest thus determined should be recorded and should be below 15%.
- 795 If the COV of the voxel values thus determined is above 15%, the acquisition time should be increased accordingly

## **Appendix A: Acknowledgements and Attributions**

1075 The QIBA SPECT Committee followed the profile document template of 05 November 2016 proffered by the QIBA something committee, Kevin O'Donnell, principal editor, to whom we are grateful for continuous guidance.

The SPECT Committee is grateful to the pioneering work of the CT Volumetry Committee, and particularly to the FDG PET Committee, for extensive guidance on how to create this profile.

1080 This Profile benefited extensively from the Japanese Quantitative Imaging Biomarker Alliance (QIBA-Japan). Responses to their many thoughtful, constructive, and collegial suggestions can be found throughout the document.

This work was made possible by the professional staff of the Radiological Society of North America reporting up through Fiona Miller and Linda Bresolin, PhD. Julie Lisiecki usually took the lead, and was often backed up by Joseph Koudelik and Susan Weinmann, among others.

The following people, listed in alphabetical order, contributed to the development and publication of this profile:

QIBA SPECT Biomarker Committee Participants	
Patrick Cella, MSc	GE Healthcare
Yuni Dewaraja, PhD (Co-Chair)	University of Michigan
John Dickson, PhD (Task Force Co-Chair)	University College London (UK)
Rachid Fahmi, MSc, PhD	Siemens
Eric Frey, PhD	Johns Hopkins
Hidehiro Iida, DSc, PhD	National Cerebral & Cardiovascular Center - Research Institute (Osaka, Japan)
Abhinav K. Jha, PhD	Johns Hopkins
S. Cheenu Kappadath, PhD	University of Texas MD Anderson Cancer Center
Paul E. Kinahan, PhD, FIEEE	University of Washington
Gregory Klein, PhD	BioClinica, Inc.
Richard LaForest, PhD	Mallinckrodt Institute of Radiology, Washington University in St. Louis
Michael Lassmann, PhD	University of Würzburg (Germany)
Manuela Matesan, MD, PhD	University of Washington

	ansporters (continueu)
Robert S. Miyaoka, PhD (Task Force Co-Chair)	University of Washington
P. David Mozley, MD (Co-Chair)	Cornell University Weill College of Medicine
Nancy Obuchowski, PhD	Cleveland Clinic Foundation
Amy Perkins, PhD	Philips
Eric S. Perlman, MD	Perlman Advisory Group, LLC
John Seibyl, MD, Co-Chair	Molecular Neuroimaging Inc., a division of inviCRO
Anne M. Smith, PhD	Siemens
John Sunderland, PhD	University of Iowa
Pierre Tervé, MS	Keosys (France)
Benjamin M. W. Tsui, PhD	Johns Hopkins
Richard L. Wahl, MD, FACR	Mallinckrodt Institute of Radiology, Washington University in St. Louis
Johannes Zeintl, PhD	Siemens
Brian Zimmerman, PhD (Task Force Co-Chair)	National Institute of Standards and Technology (NIST)

SPECT dopamine transporters (continued)
